

Polish experiences with tunnel smoke control

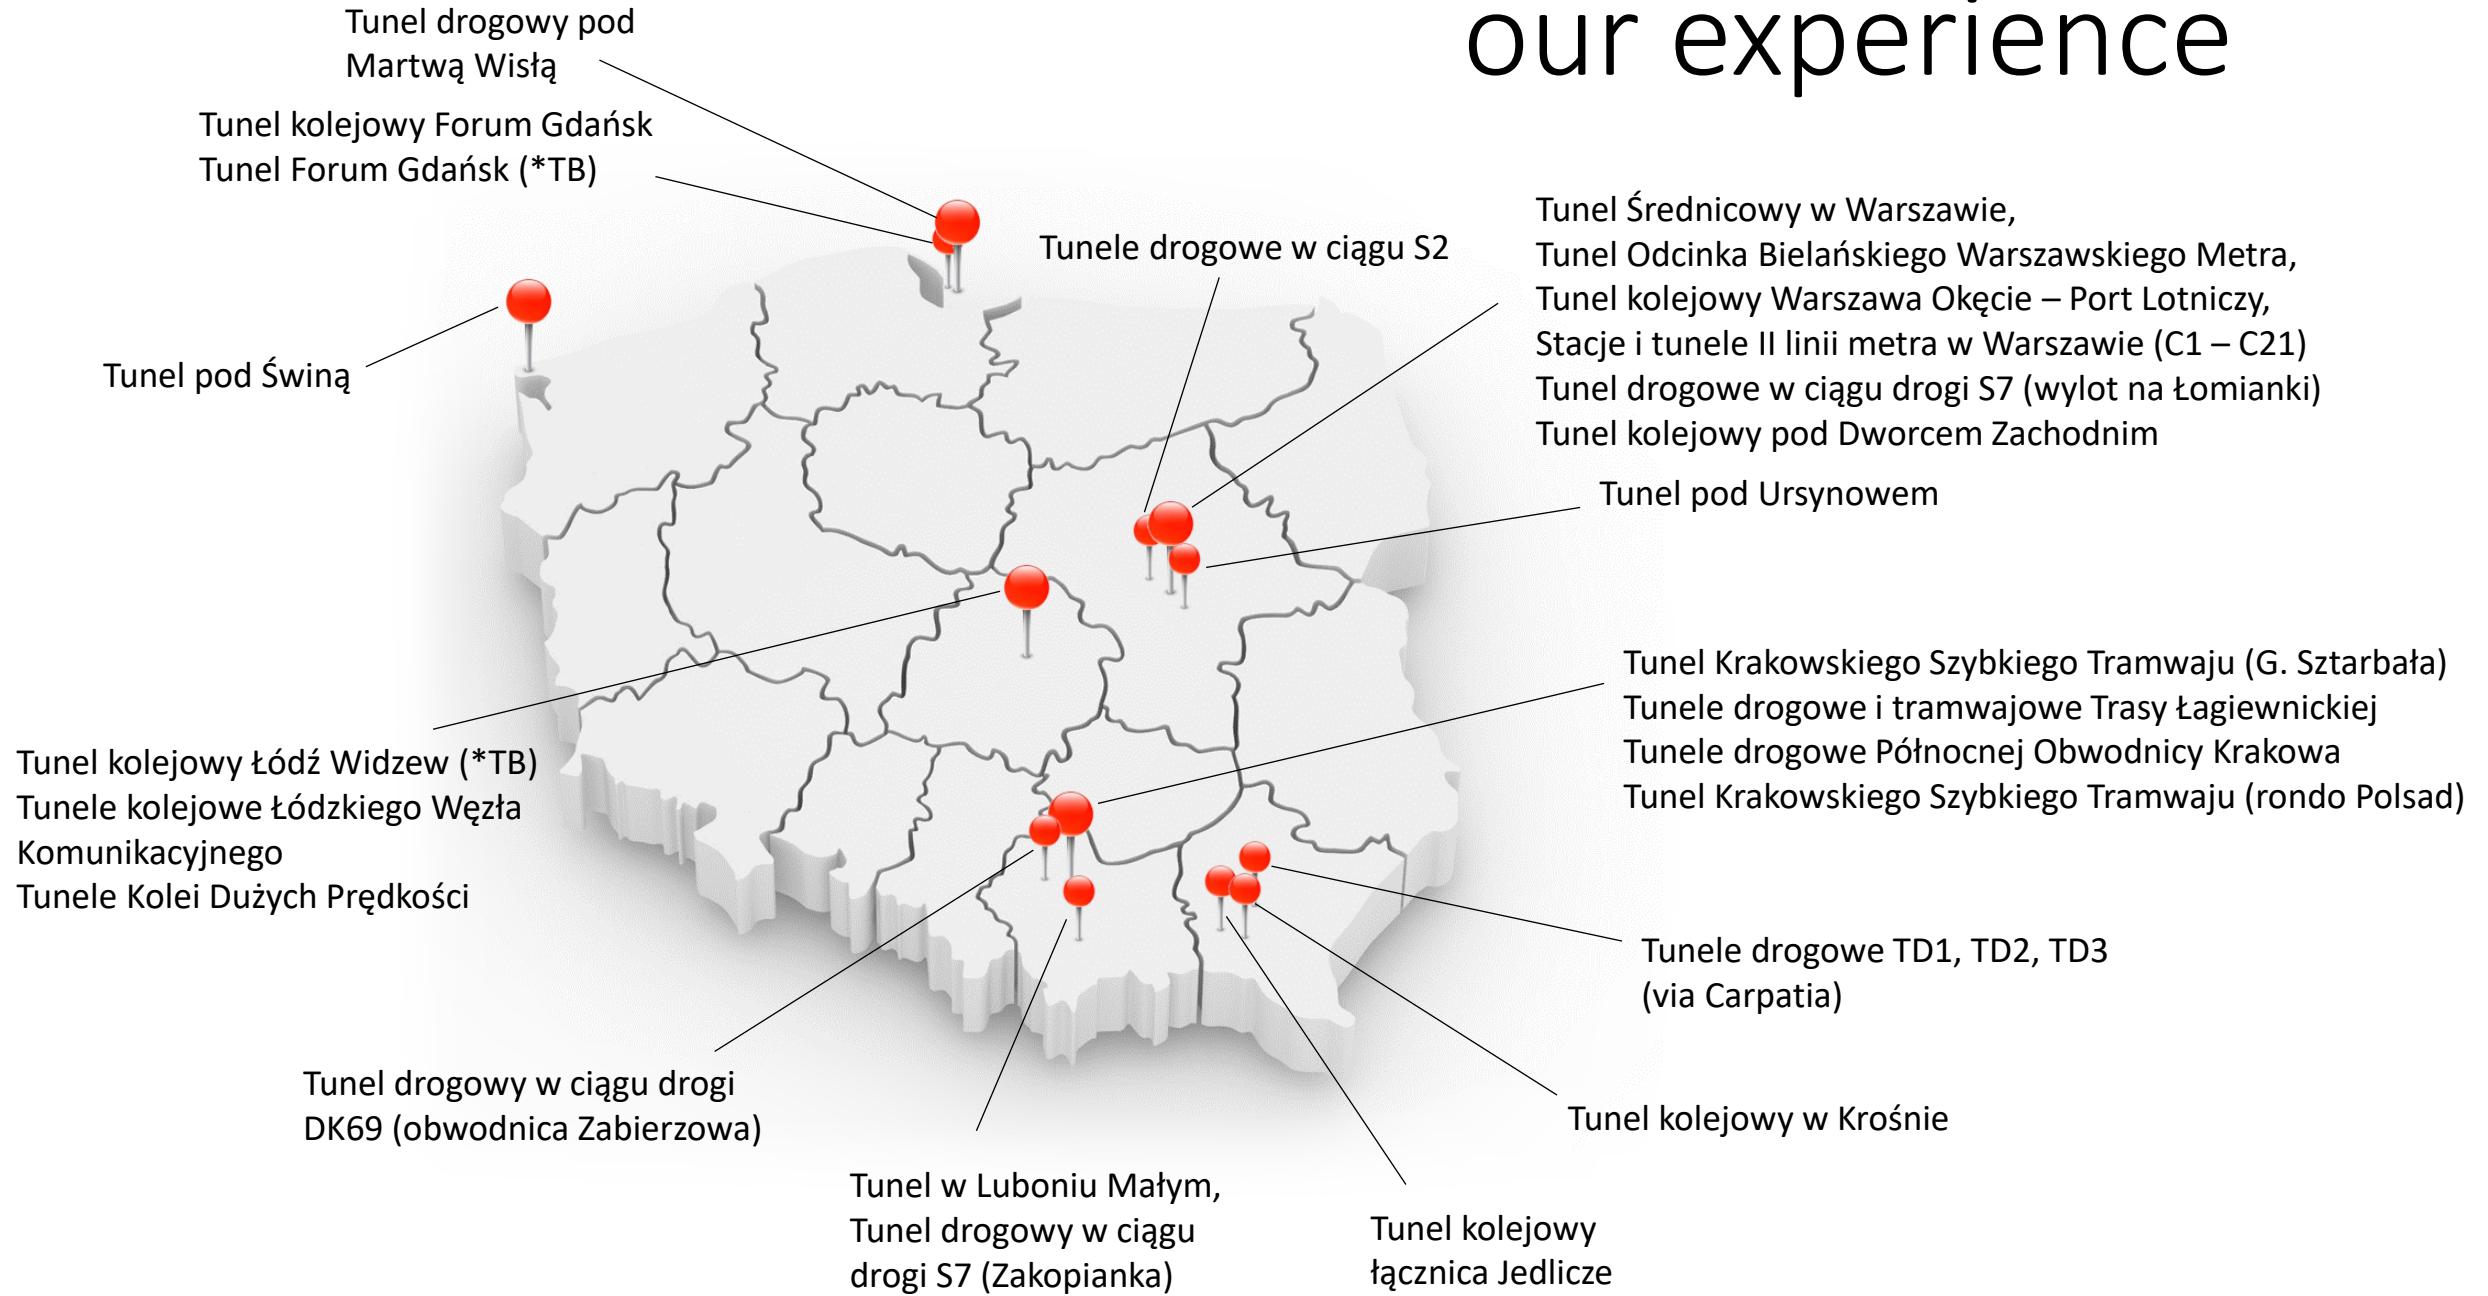

Dr Wojciech Węgrzyński, prof. ITB
Instytut Techniki Budowlanej

our experience

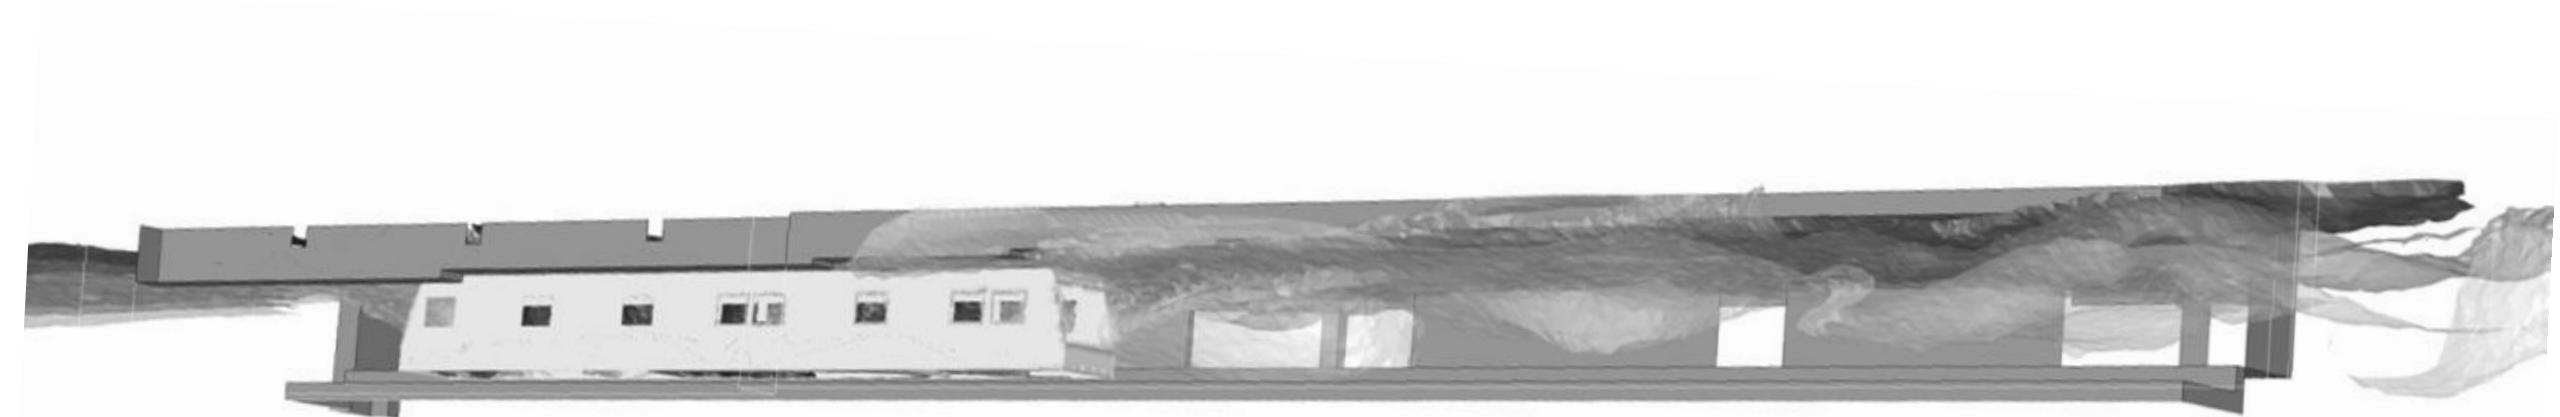

our experience

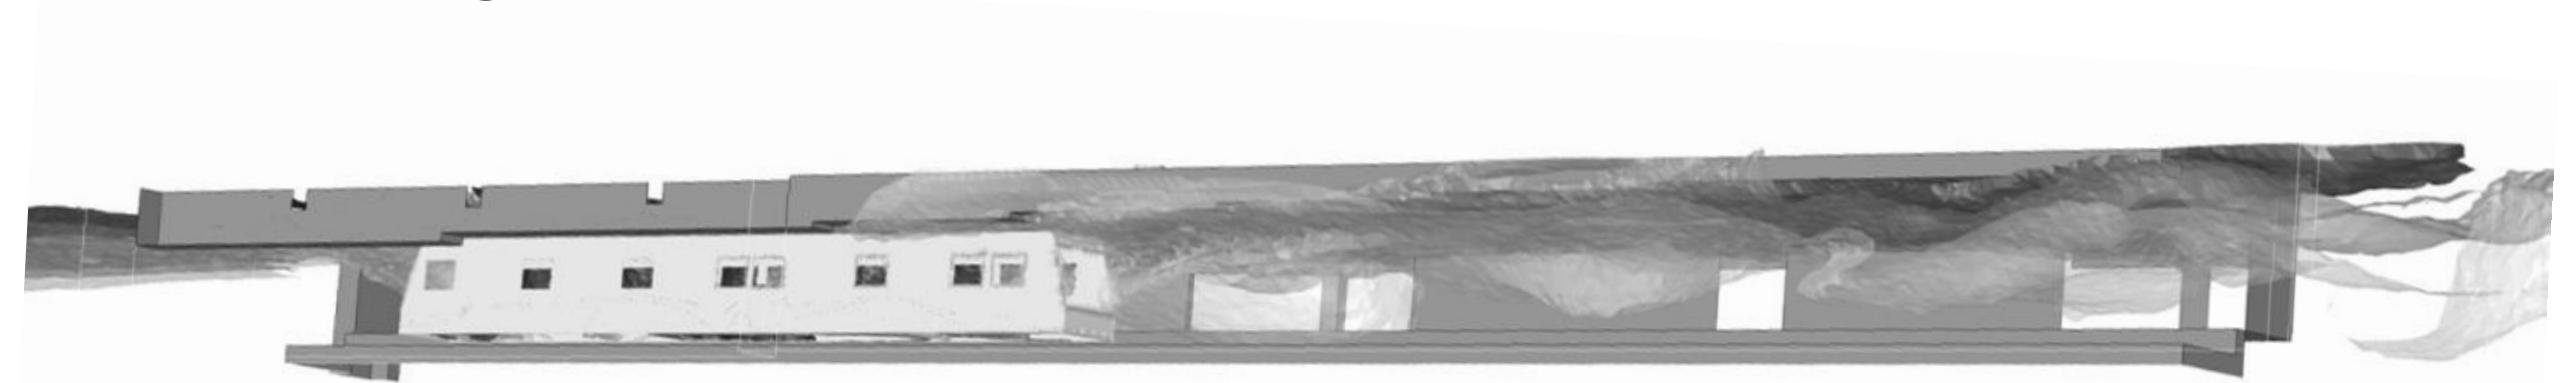

our main job - smoke control

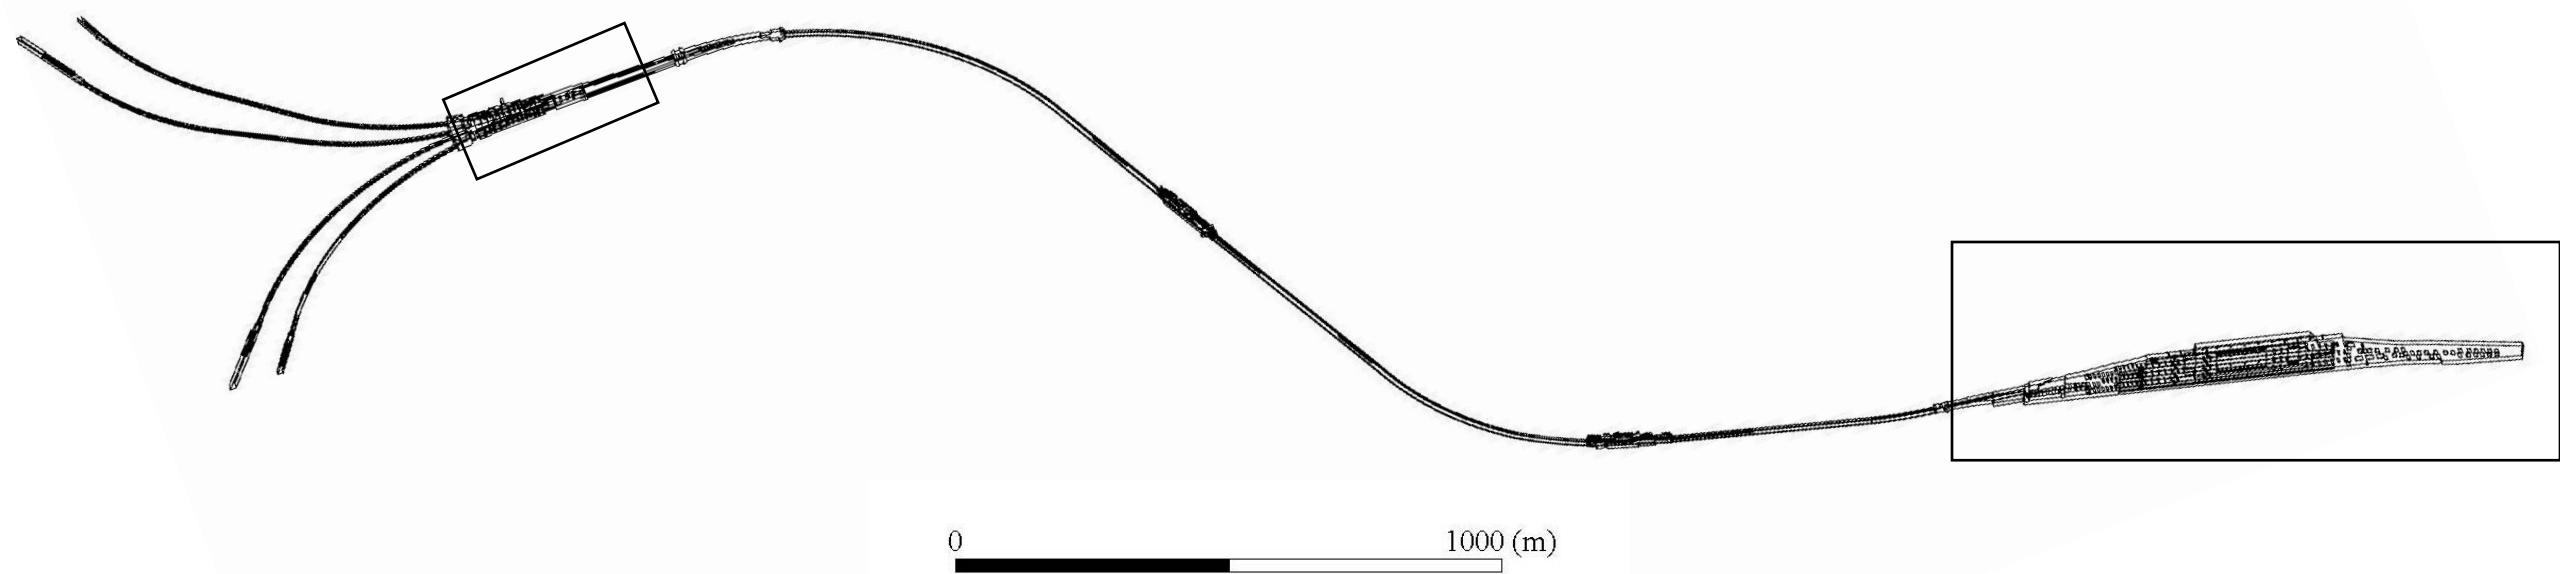

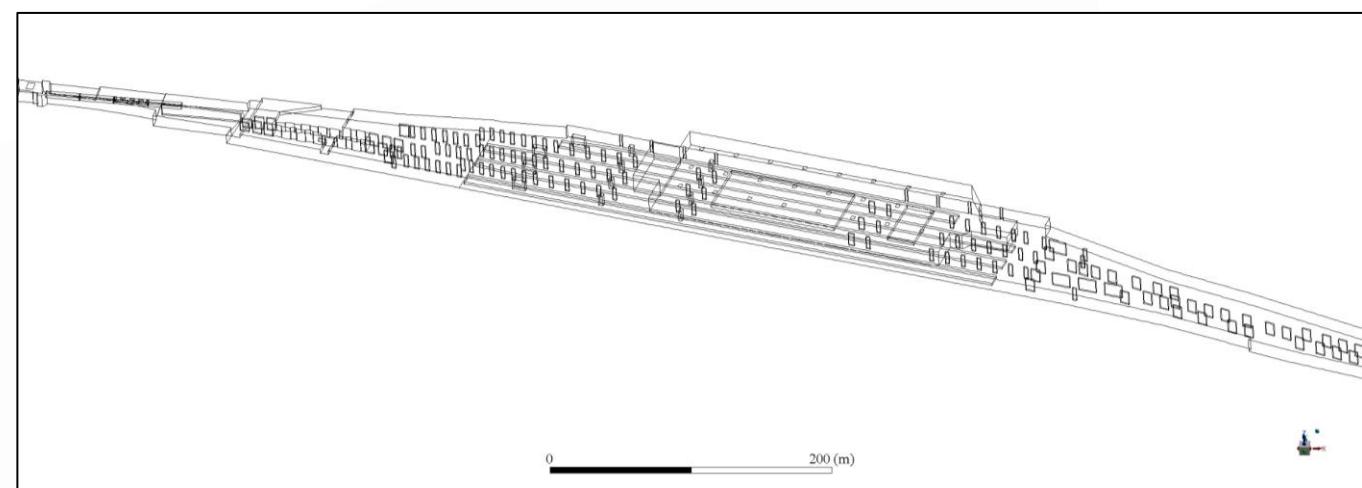

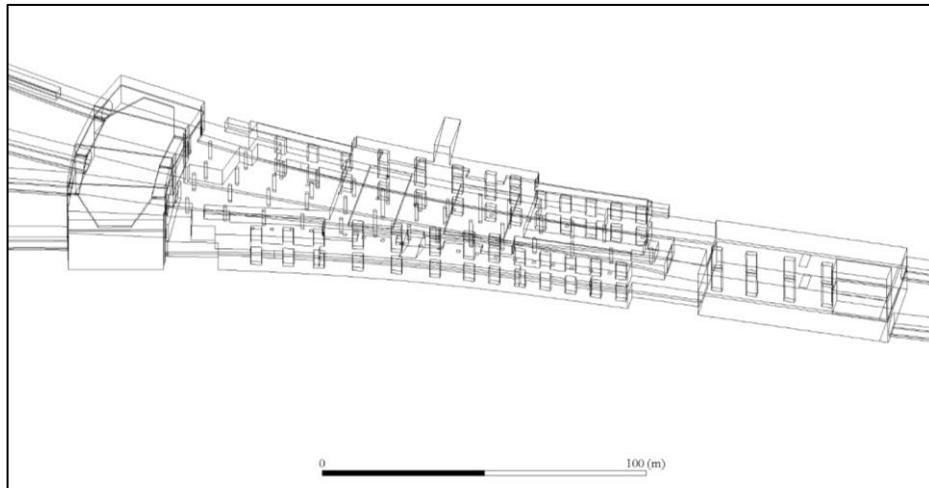

- Removes smoke and heat from the fire
- Allows to evacuate the endangered space
- Allows for successfull firefighting operation
- Reduces the consequences of fires

our main job - smoke control

- Removes smoke and heat from the fire
- Allows to evacuate the endangered space
- Allows for successful firefighting operation
- Reduces the consequences of fires
- All of the above are commonly verified with the use of CFD modeling.

smoke control system types

Horizontal venting

Smoke removed from smoke layer

Longitudinal venting

Smoke pushed along the tunnel

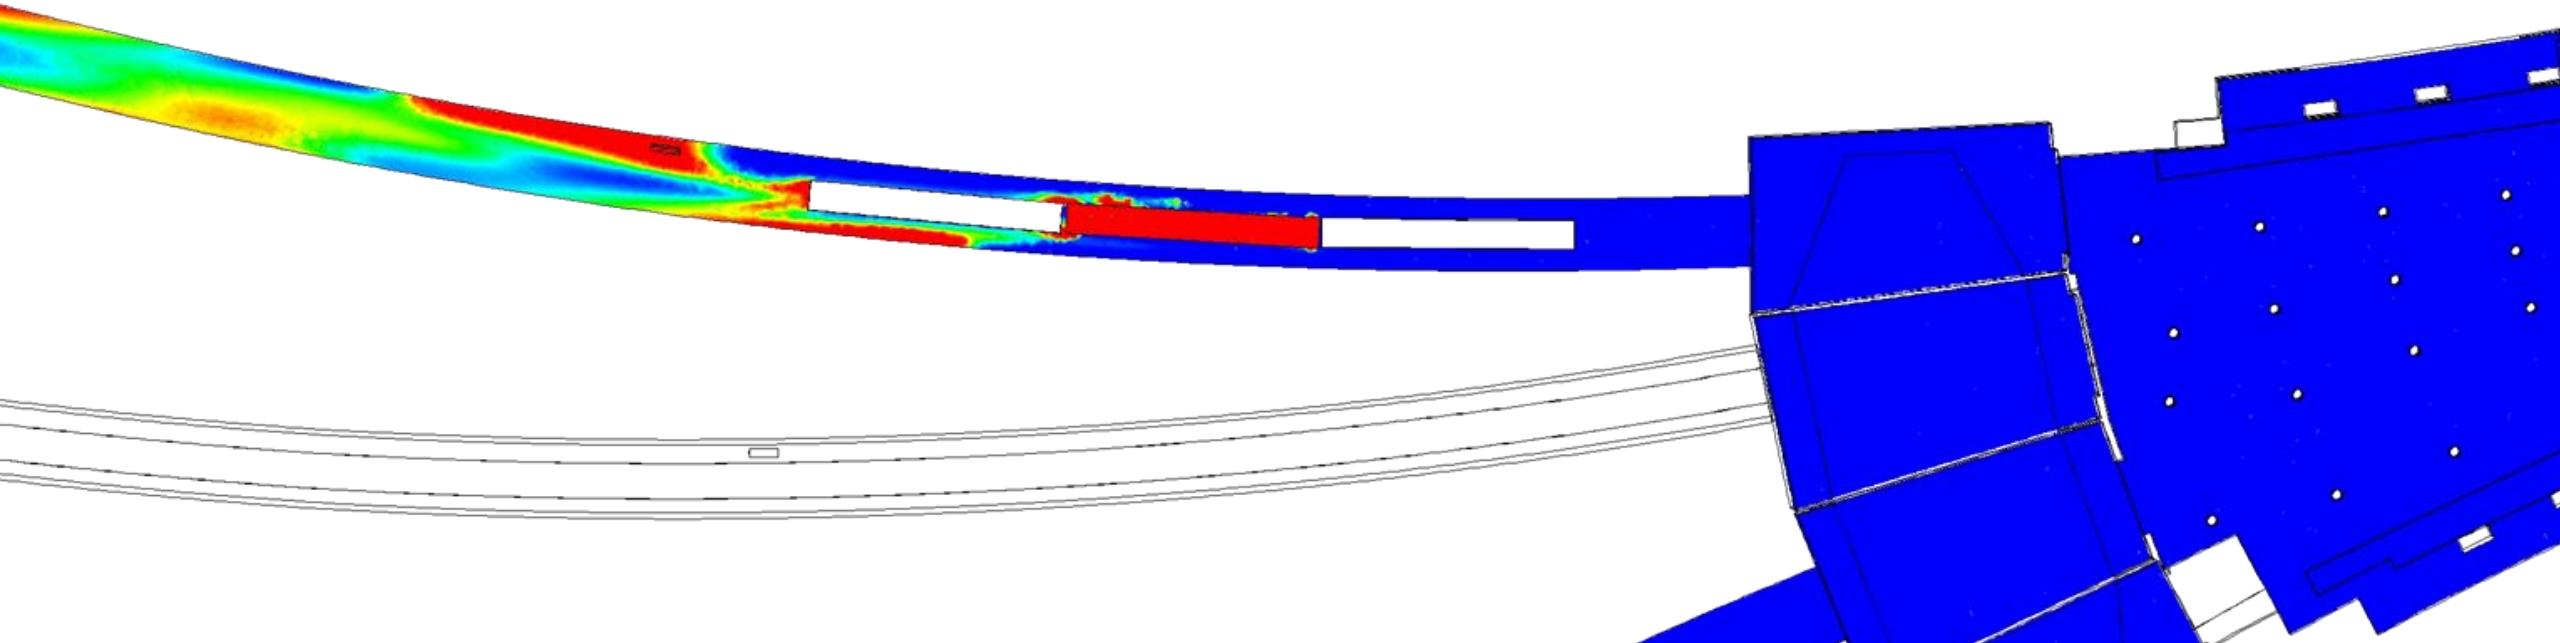

What do we want from a longitudinal system?

- 1** Low velocity Fire moving towards observer, a failed system
- 2** „Containment velocity“ reached – no real threat from backlayering
- 3** „Critical velocity“ reached, great when you need to make barbecue, but do we really need this?
(plus we make fire bigger...)

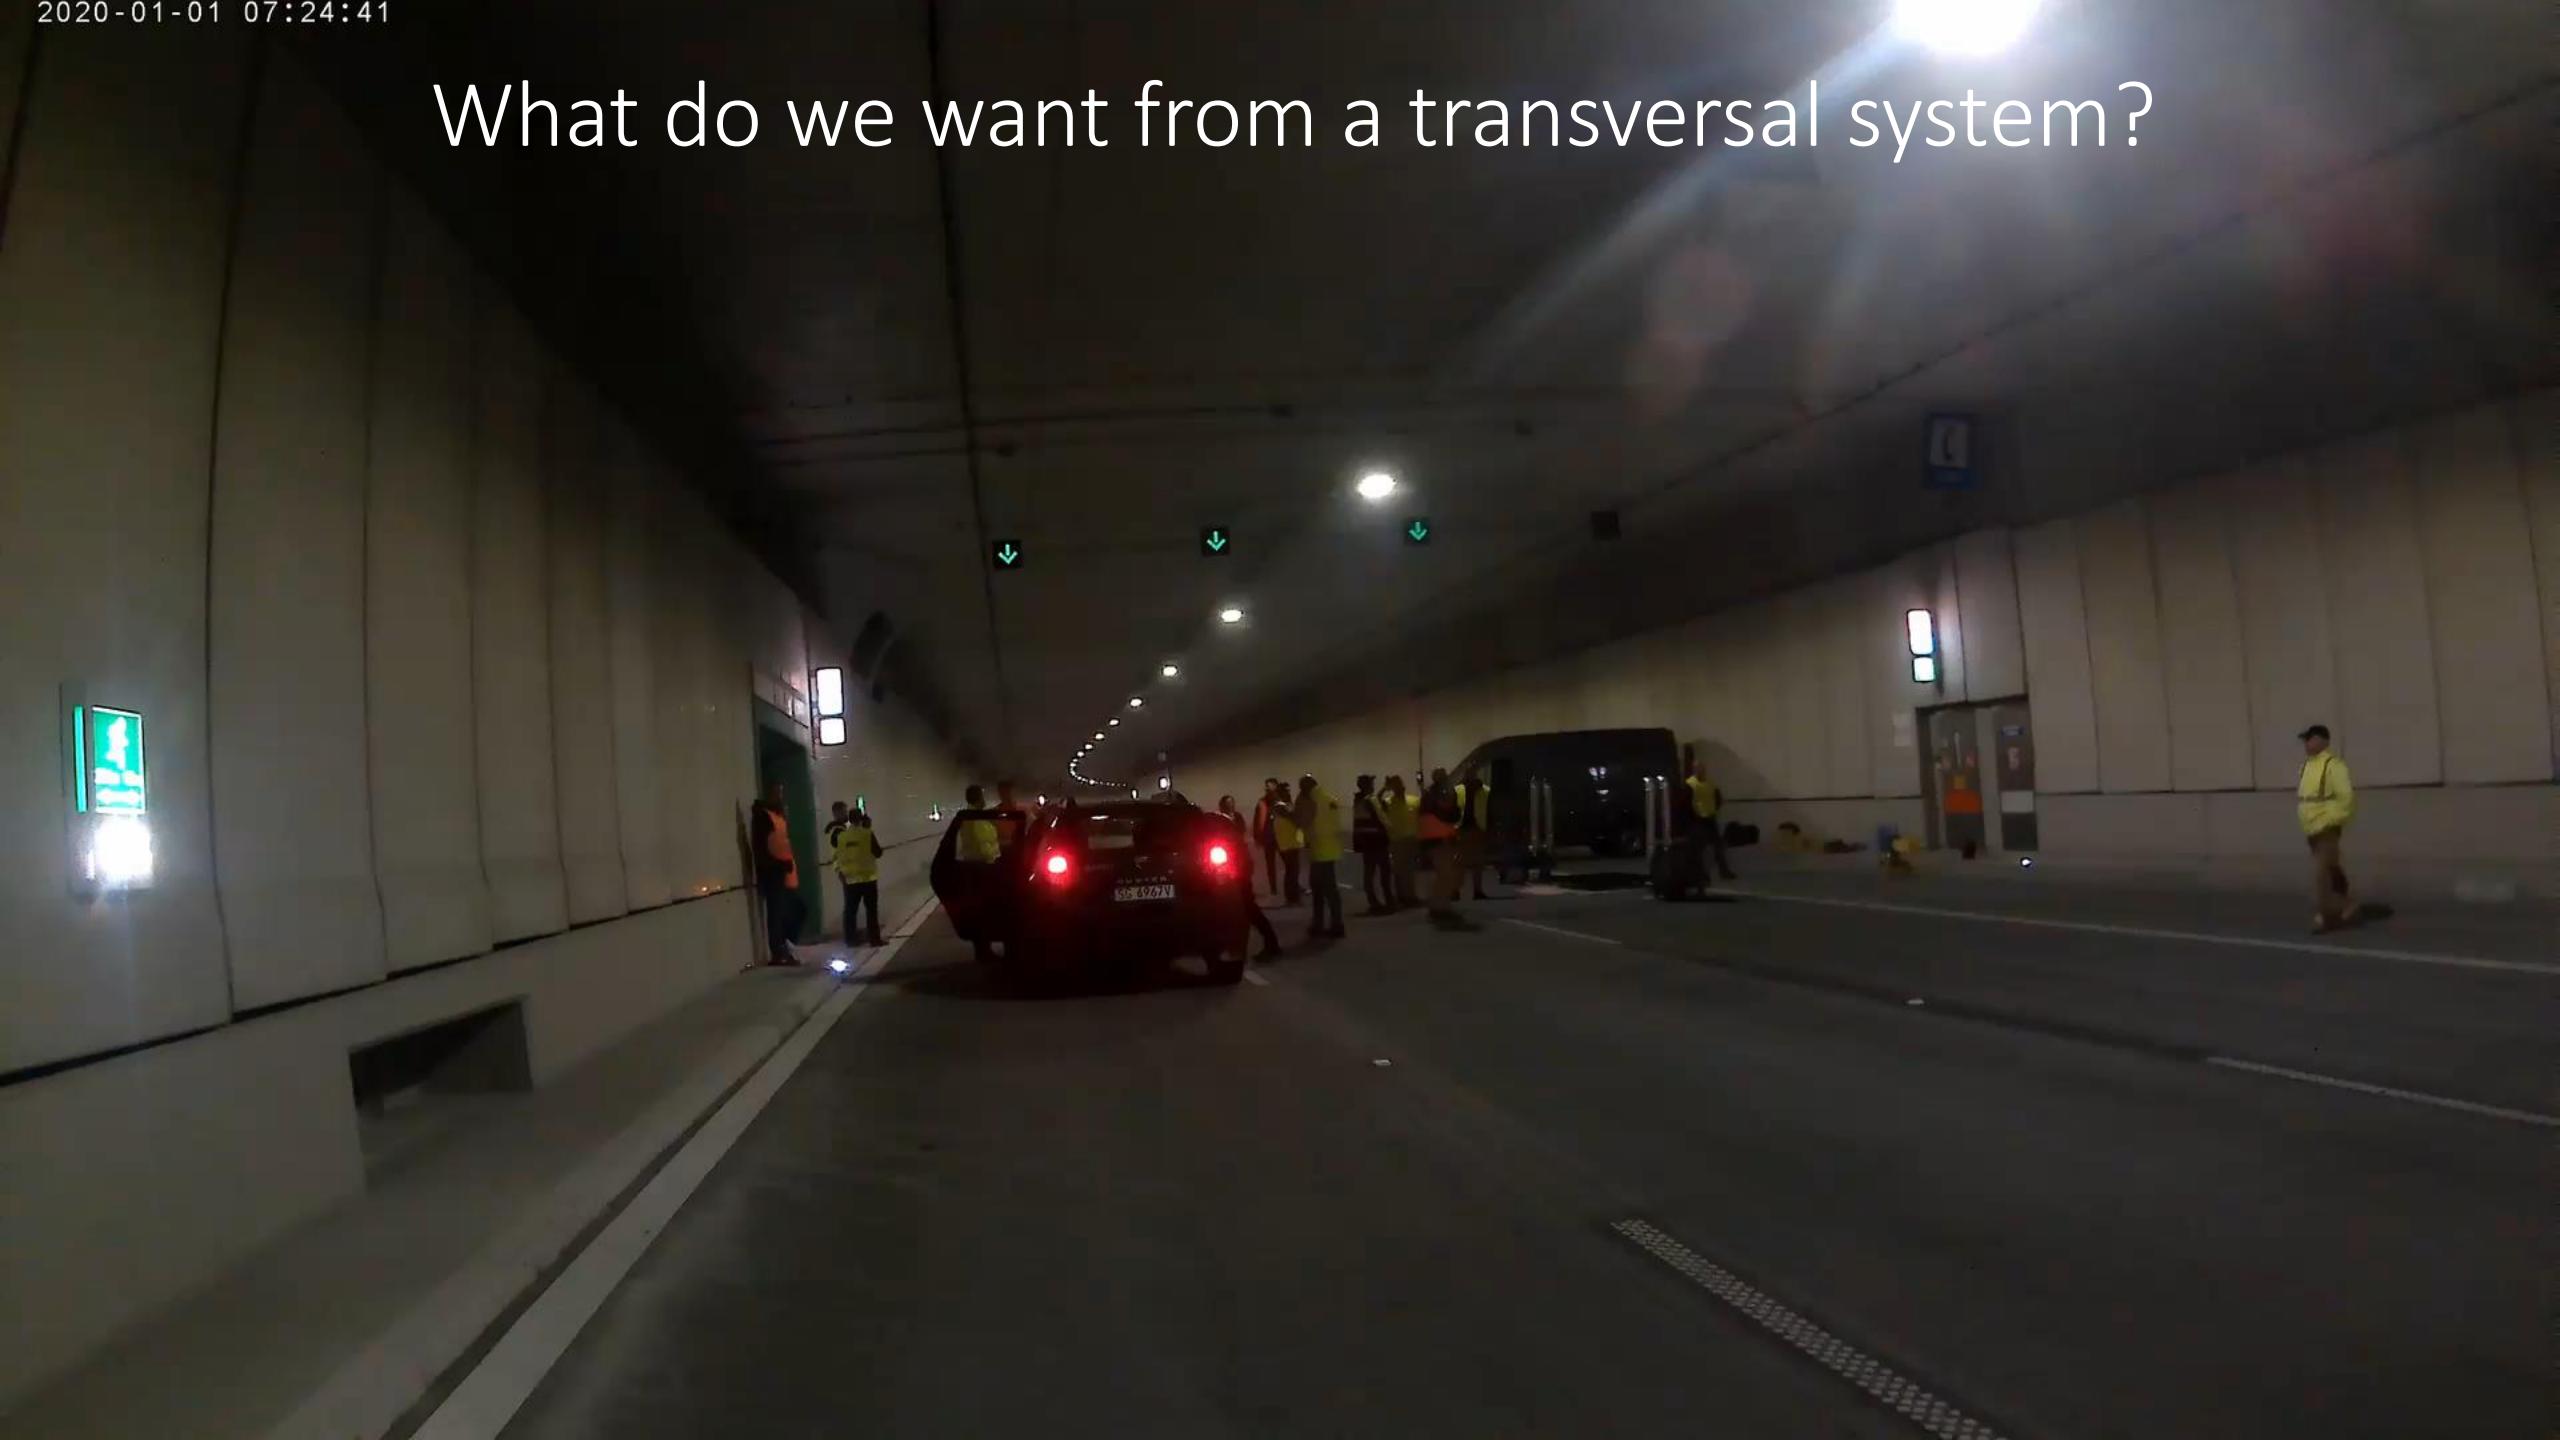

What do we want from a longitudinal system?

Moving away from overdesigned systems based on critical velocity at a combination of most onerous conditions (wind/fire/traffic) that form a low probability event – maybe we should move towards probabilistic and risk based design?

2020-01-01 07:24:41

What do we want from a transversal system?

A photograph showing a large-scale fire simulation on a highway ramp. A massive plume of white smoke rises from a burning vehicle or trailer. Several firefighters in yellow vests are visible, some standing near the flames and others further back. The scene is set at night or in low light, with the fire providing most of the illumination.

challanges

- mitigation of complex wind conditions that can overwhelm the system
- inability to represent initial conditions from traffic in the system design

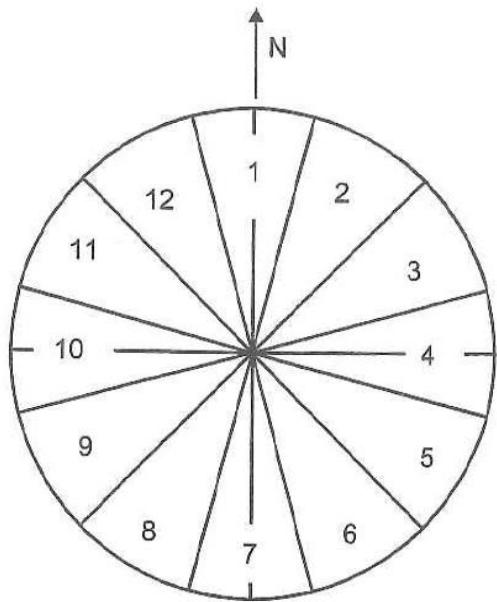

wind influence

$$\Delta P := \Delta P_{wind} \cdot A_{koreskcyjne} + \Delta P_{chimneyRtm} + \Delta P_{entrance} + \Delta P_{down} + \frac{\Delta P_{exit}}{A_{koreskcyjne}} + \Delta P_{veh} + \Delta P_{fire} + \Delta P_{atm} = 111 \text{ Pa}$$

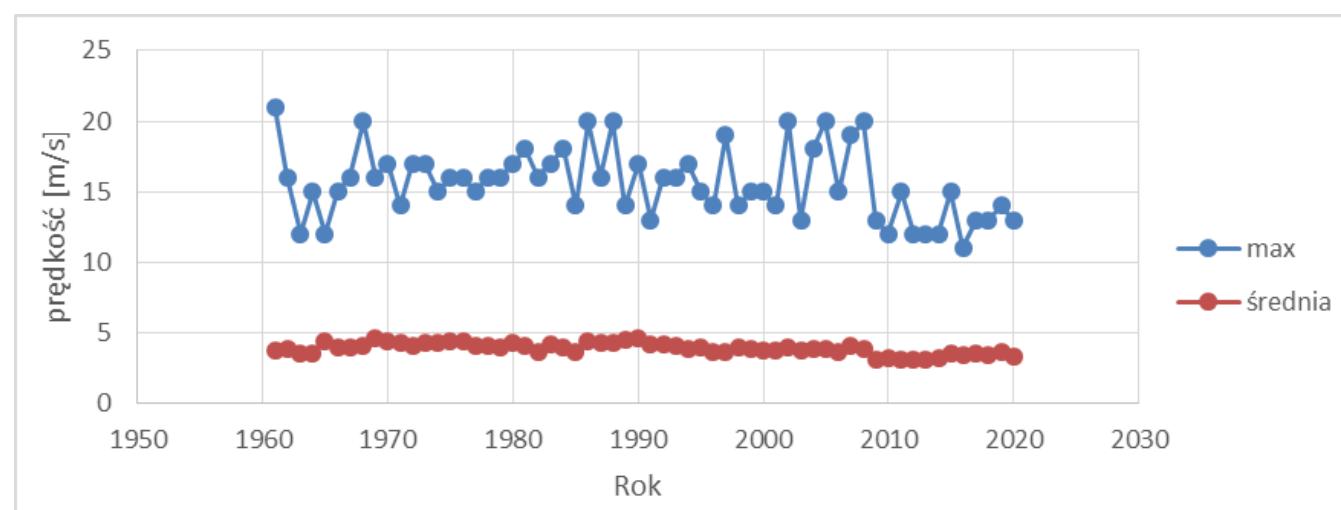

Wind was included in the design stage by introducing jet-fan systems in the design, but there is no good method to define their momentary mode of operation.

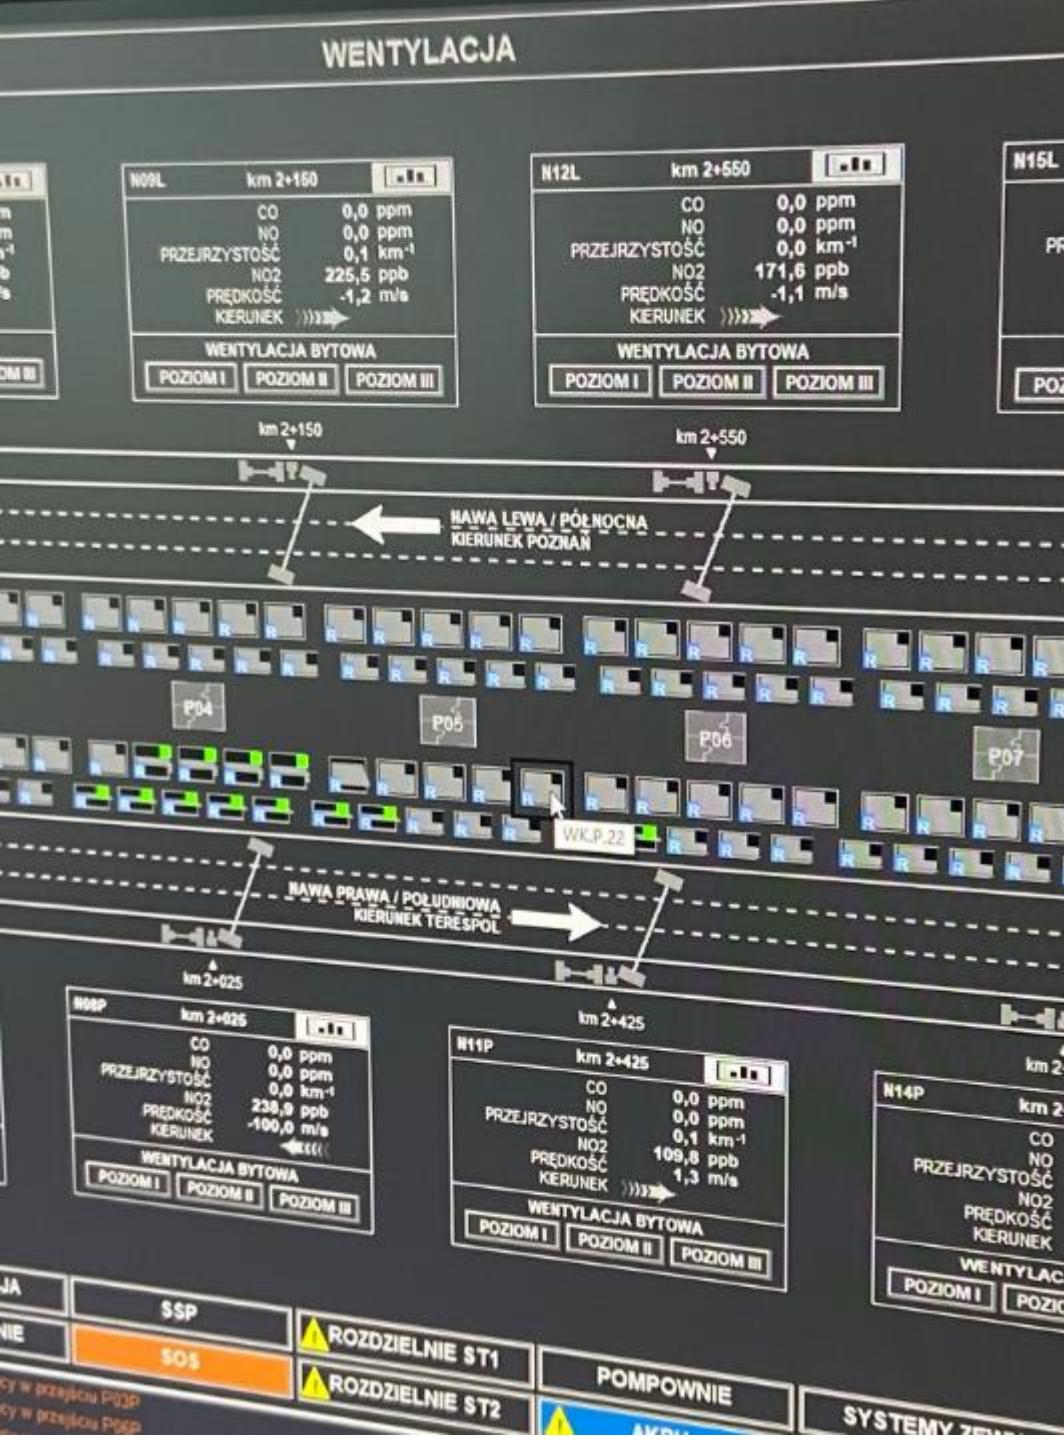

wind influence - solution

WENTYLACJA

wind influence - solution

Because we knew exactly what velocity in the tunnel is introduced by every particular wind velocity/direction combination (either measured or calculated from estimated portal coefficients), we could have designed individual scenarios of operation of the jet-fans for any wind speed that will occur.

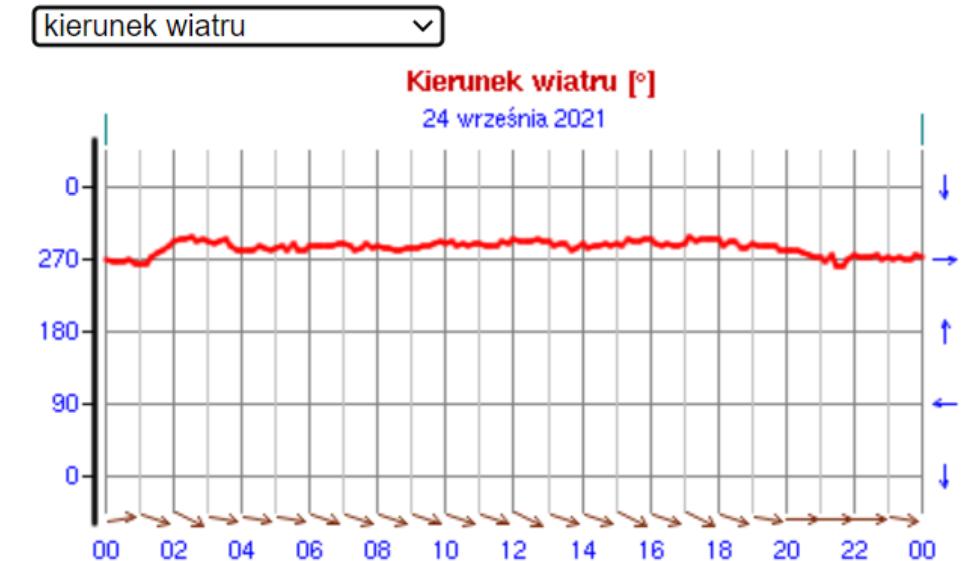

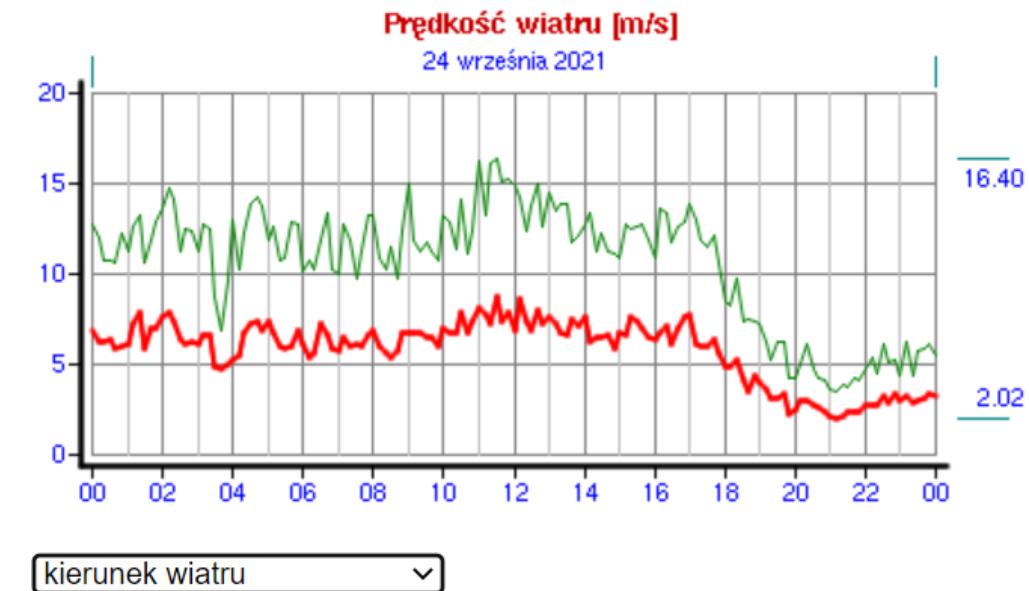

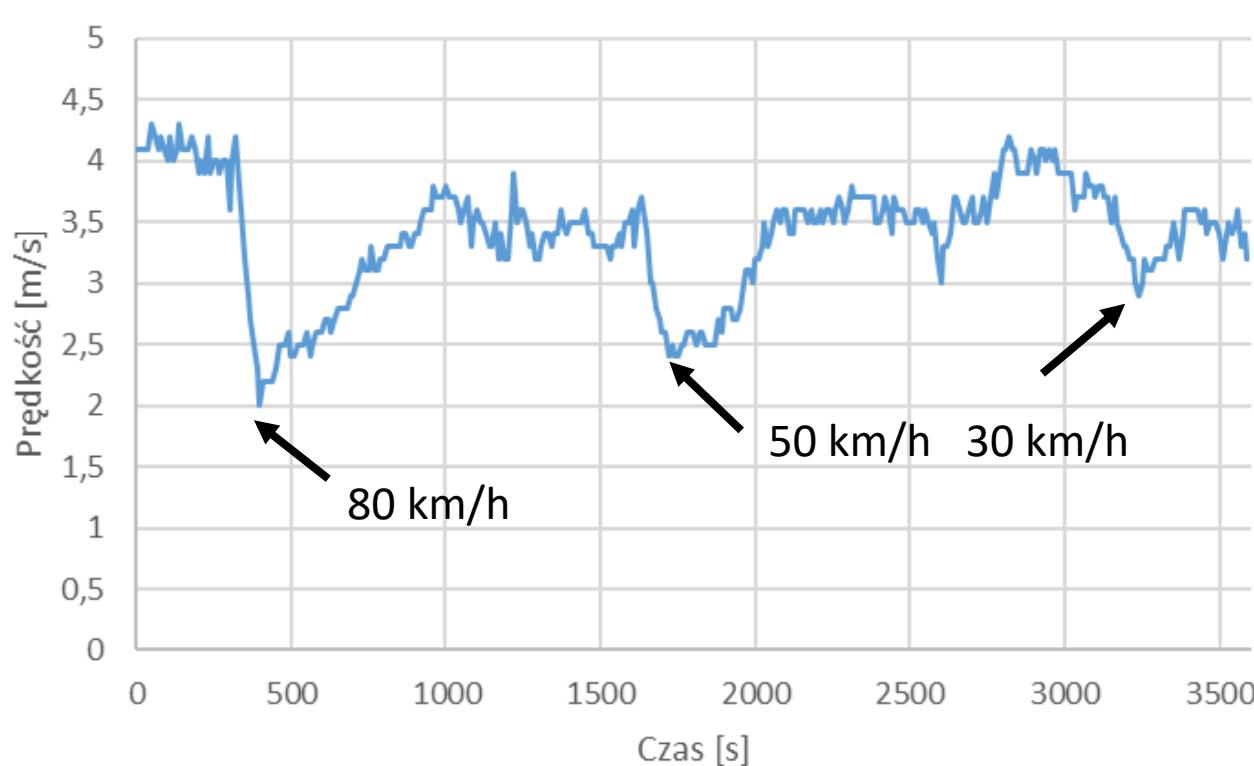

Can vehicles stop wind?

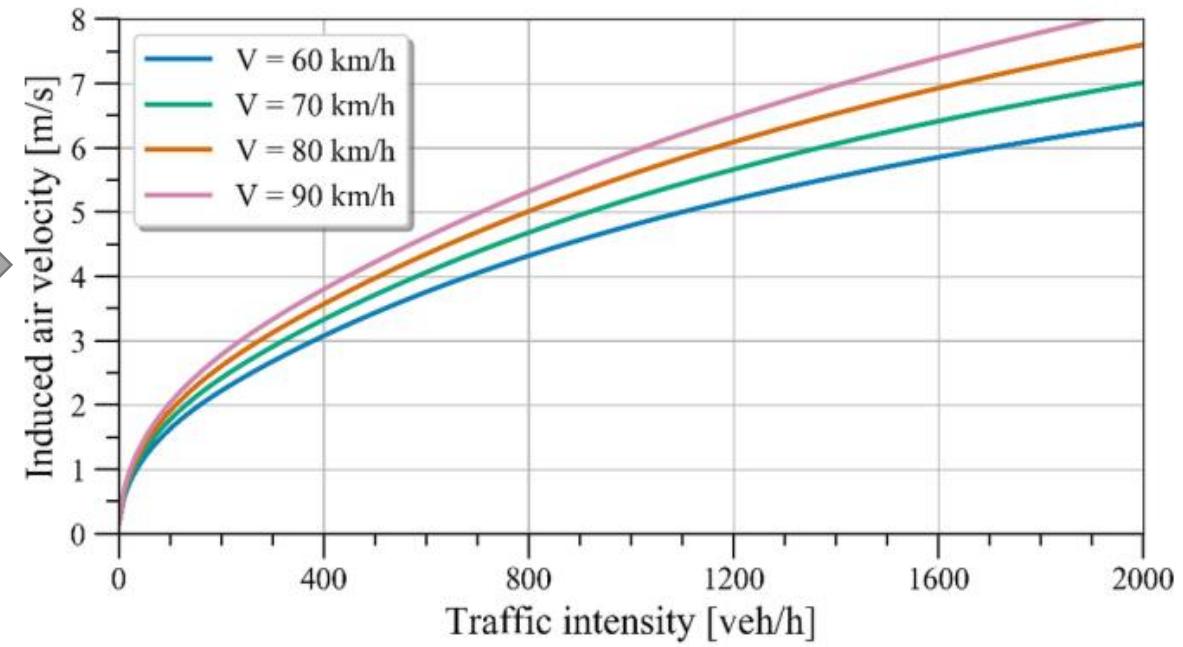

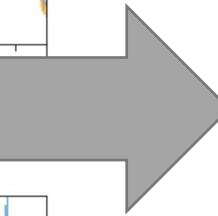

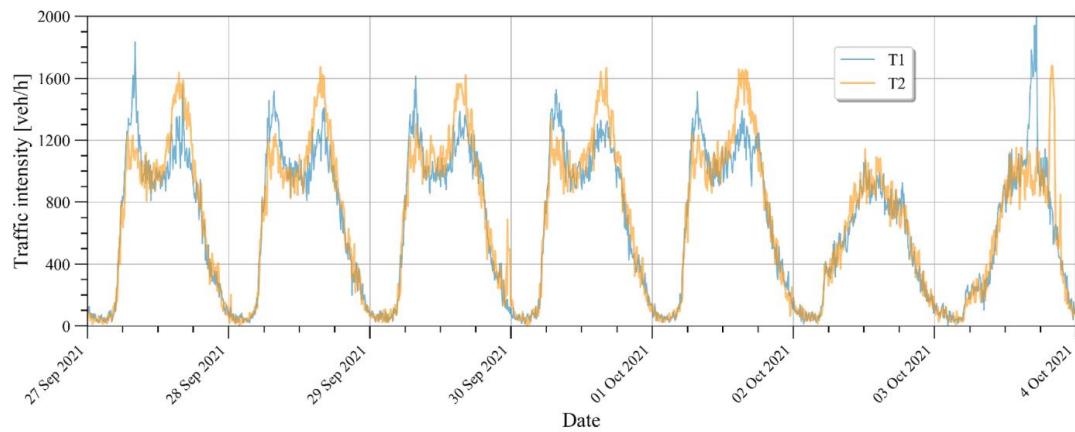

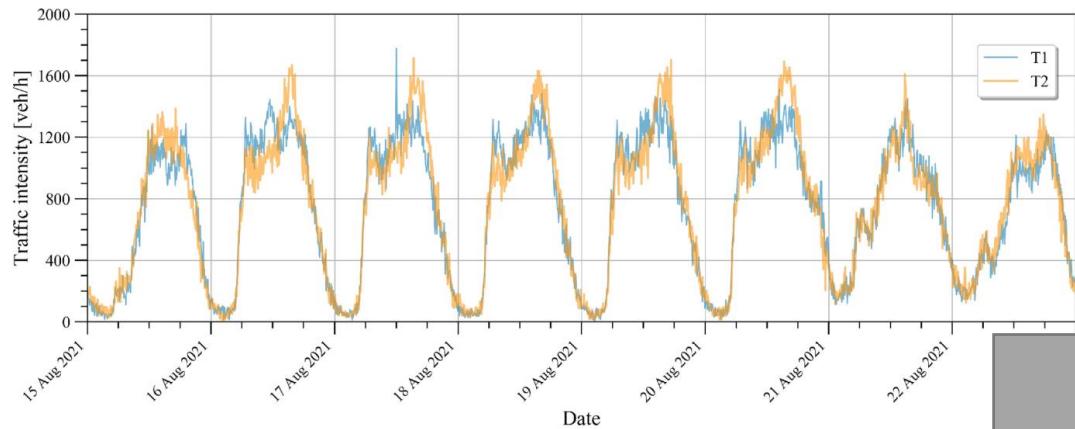

Can vehicles stop wind?

Can vehicles stop wind?

Can vehicles stop wind?

a)

Fig. 13. Traffic intensity for both periods.

Król A., Król. M., Węgrzyński W., 2022. A study on airflows induced by vehicle movement in road tunnels by the analysis of bulk data from tunnel sensors. (in review)

Our little innovation

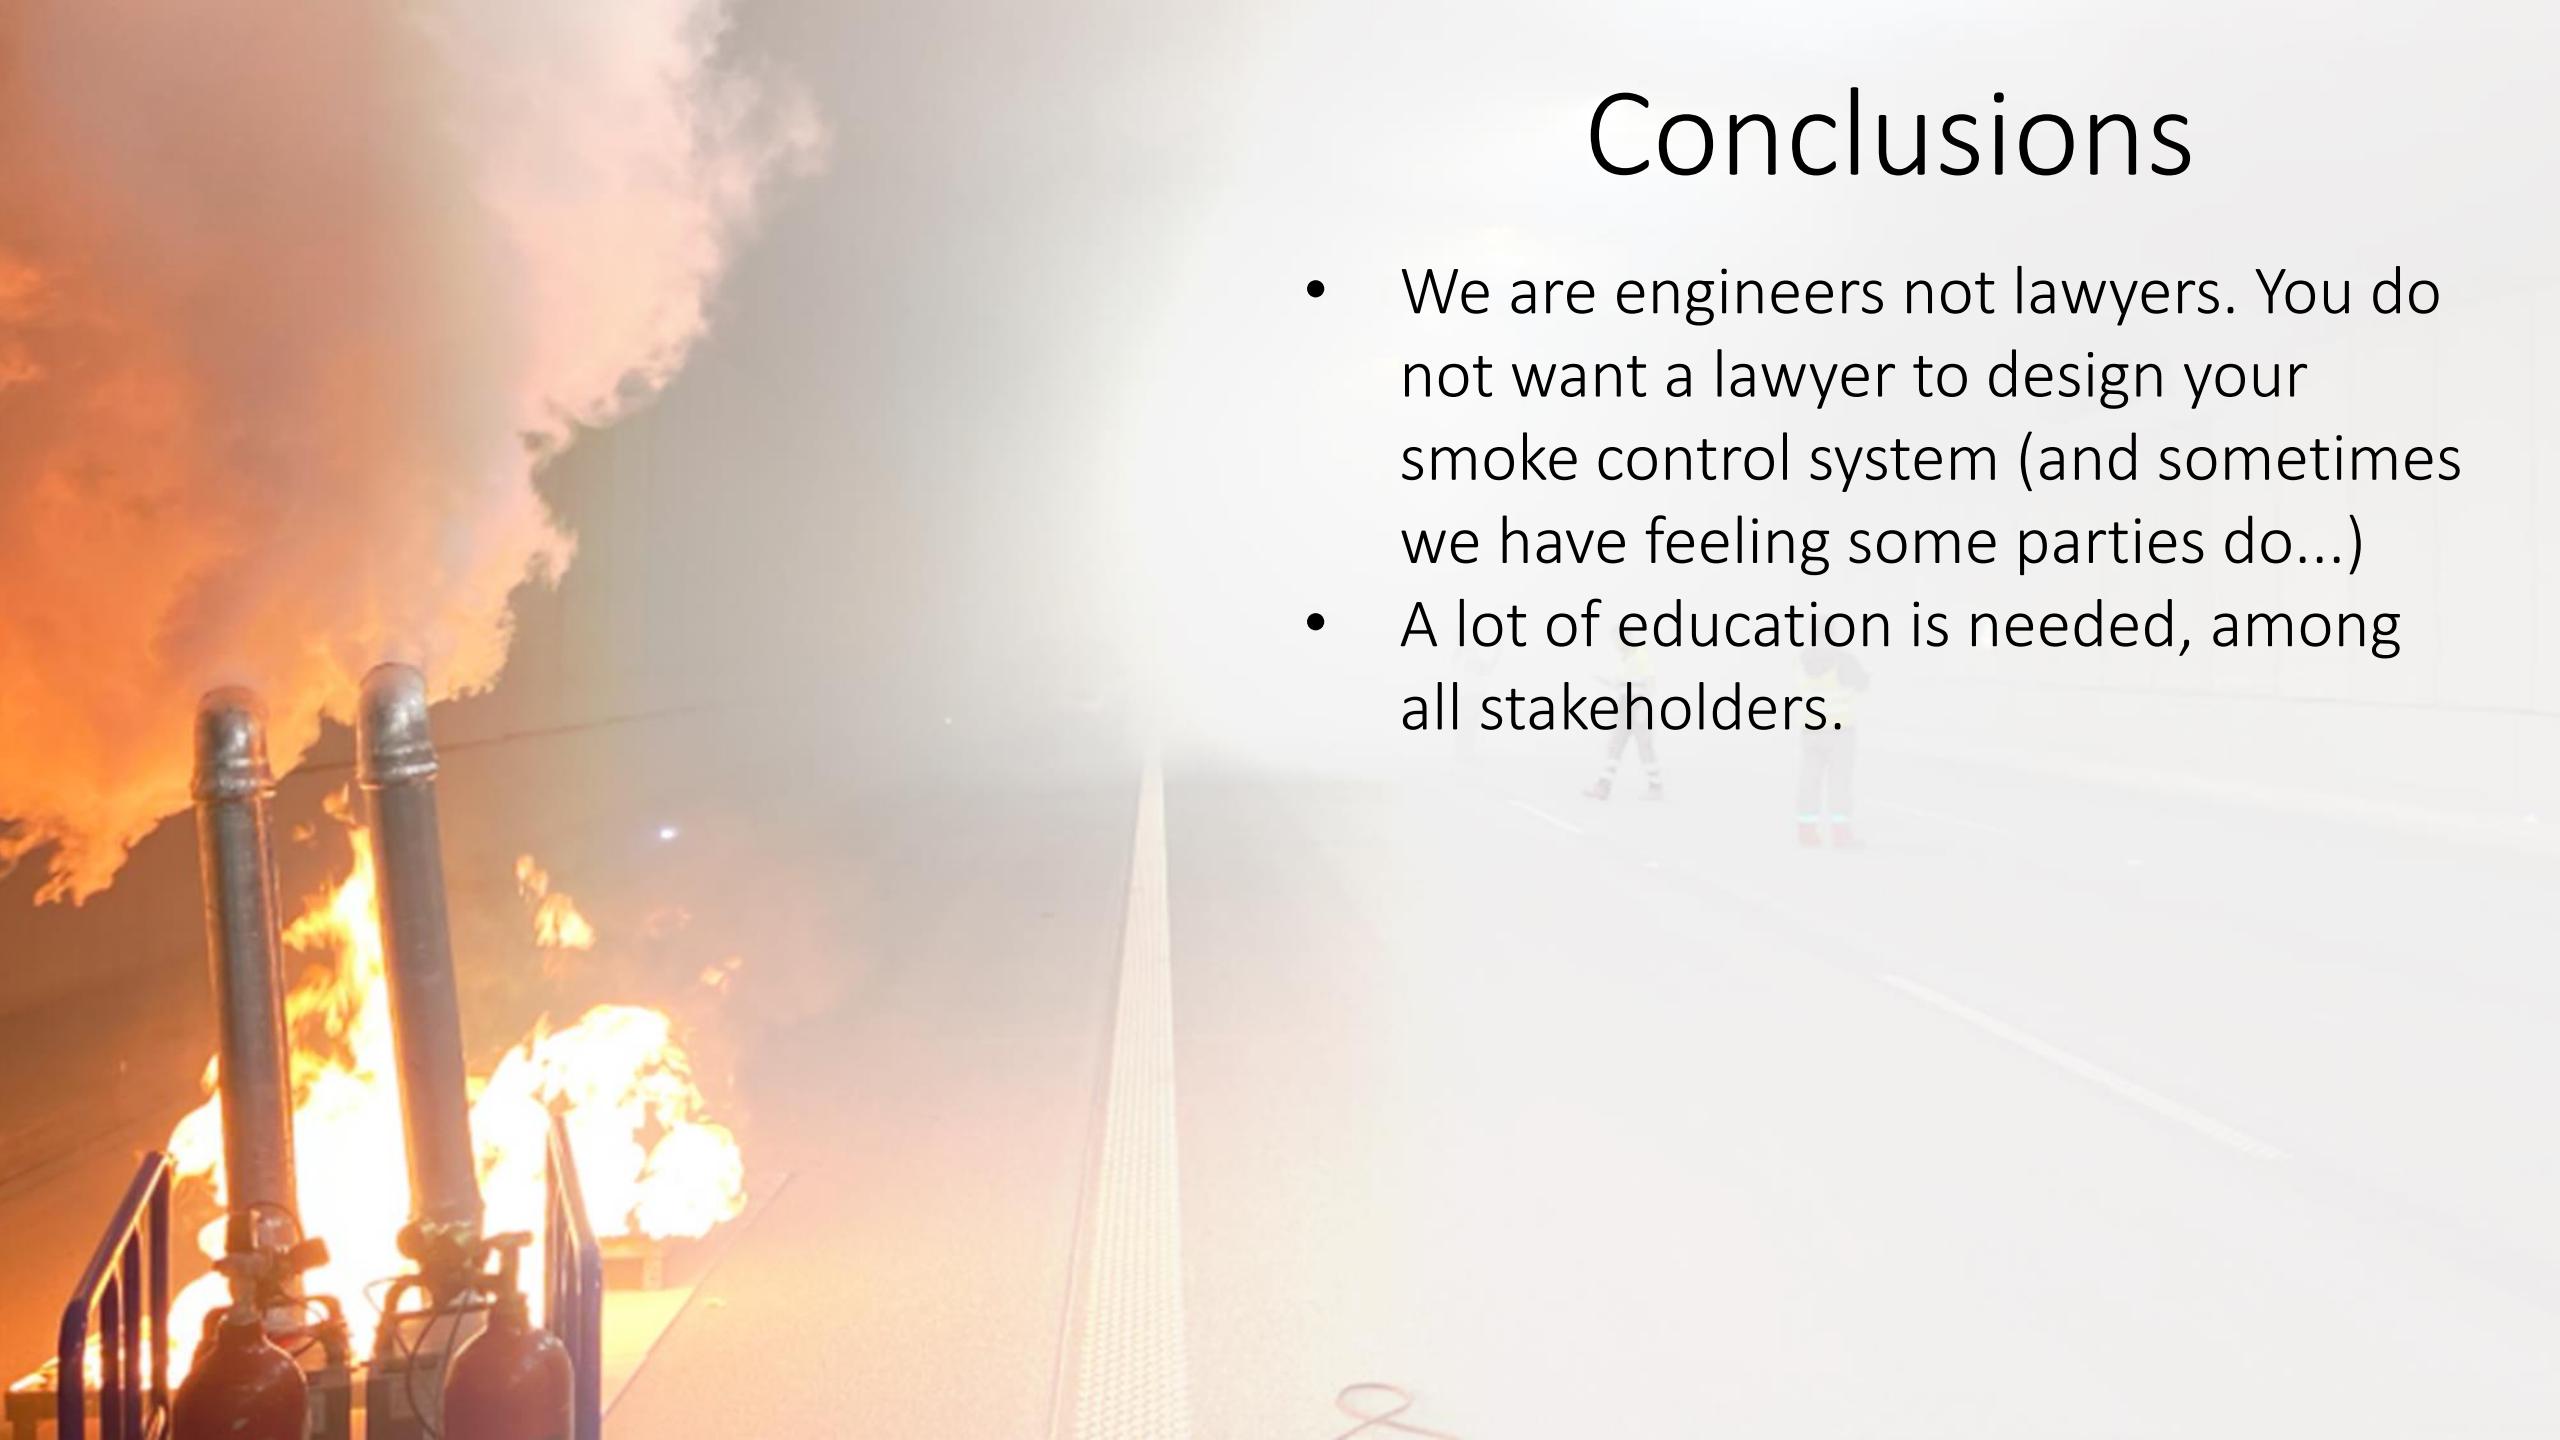

Every fire in the tunnel starts with a vehicle that has stopped.

Using AID and SCADA systems we have programmed an additional sanitary mode operation mode, which is like the fire mode operation, that is triggered once a vehicle stops in the tunnel. This allows to significantly shorten the time for the system to operate in full capacity (as fire detection may take some time...)

A photograph of an industrial facility at night or in low light. In the foreground, several vertical pipes and cylindrical tanks are visible, some with bright orange and yellow flames erupting from them. A large plume of dark smoke or steam rises from the facility, partially obscuring the background. The scene conveys a sense of industrial activity or perhaps an accident.

Conclusions

- There are so many tunnels built in Poland, our job security seems great 😊
- Mainly longitudinal systems, designed with industry best practices...
- ... but that does not mean we do not aspire higher – we can design these systems better to achieve more optimal cost-benefit ratio.

A photograph of an industrial facility at night or in low light. In the foreground, several vertical pipes and valves are visible, some with bright orange and yellow flames erupting from them. A large plume of thick, dark smoke or steam billows upwards from the left side of the frame. The background is dark, suggesting a nighttime or low-light environment.

Conclusions

- We are engineers not lawyers. You do not want a lawyer to design your smoke control system (and sometimes we have feeling some parties do...)
- A lot of education is needed, among all stakeholders.

Thank you!
